Glomerulonephritis Associated with Bacterial Infection

The Emerging Role of Staphylococcus

Tibor Nádasdy, MD
Clinical history (Case #1)

- 60-year-old Caucasian male with insulin dependent DM, diabetic neuropathy, CAD, HTN, obesity.
- Presented with gangrene of left great toe.
- Blood and wound cultures positive for methicillin sensitive Staphylococcus aureus.
- Zosyn and vancomycin were started.
- After two days, amputation of the left great toe was performed.
- After surgery, he developed oliguria (425 ml per day) and over 6 days, serum cr. increased from 1.1 mg/dl to 3.8 mg/dl.
- Active urine sediment, Urine pr/cr 3.2, serum complement levels normal.
Glomerular intracapillary hypercellularity
Glomerular capillaries contain inflammatory cells. Note neutrophil granulocytes [n] and eosinophil granulocytes [eo].
Acute tubular necrosis, affected tubules are lined by flat, irregular epithelium.
Strong primarily mesangial granular staining for IgA
Immune complex deposits also stain for C3
Expanded mesangium with electron dense immune-type deposits (arrows)
Mesangial electron dense immune-type deposits
Few scattered immune-type deposits along the glomerular capillary loops, slightly thickened GBM.
Diagnosis

• Active intracapillary proliferative glomerulonephritis with IgA and C3-containing immune complex deposits, consistent with *Staphylococcus aureus* infection associated glomerulonephritis (SAIGN).

• Moderate diabetic nephropathy with mainly diffuse diabetic glomerulosclerosis.
Follow-up

• Infection was successfully treated, renal function slowly improved

• Follow-up after 4 years and 5 months:
  – Serum creatinine stable at 2.0 mg/dl.
  – Blood pressure controlled.
  – Lasix daily, with low salt diet
  – Other problems – gastric ulcer with bleeding and anemia, diabetes, HTN, peripheral vascular disease.
Bacterial infections and glomerulonephritis

**Post-infectious /post-streptococcal glomerulonephritis**

“Post” – after infection resolves with or without anti-microbial treatment

Latent period of 1 to 4 weeks with normal state of health

Acute onset of glomerulonephritis

**Glomerulonephritis with active ongoing infection**

- **Staphylococcus infection associated glomerulonephritis** (usually IgA dominant)
- **Glomerulonephritis with other persistent infections**
  - Endocarditis
  - Deep seated abscesses
  - Shunt nephritis

\({}^a\) In seven patients, cultures grew two or three bacteria (staphylococcus and *E. coli* in three; staphylococcus and enterococcus in one; staphylococcus and *S. marcescens* in one; *E. coli* and enterococcus in one; and staphylococcus, proteus, and pseudomonas in one).

\({}^b\) Including five patients with infection by enterococci (group D streptococci).

---

Staphylococcus infection associated glomerulonephritis (SIAGN)

• In developed countries, the incidence of post-streptococcal GN has declined because of successful treatment of acute streptococcal infections.

• Staphylococcal infection-related glomerulonephritis is on the rise because
  – 1. Emerging drug-resistant strains of Staphylococcus and both nosocomial and community-acquired staphylococcal infections.
  – 2. The growing elderly population with increasing prevalence of comorbidities, such as diabetes and morbid obesity

• Infection is ongoing at the time the glomerulonephritis is diagnosed. Therefore the term “post”-infectious is a misnomer and should not be used.

• IgA-dominant or co-dominant immune complexes are commonly seen, posing a diagnostic pitfall with idiopathic IgA nephropathy (and Henoch-Schönlein purpura).
Characteristics of staphylococcus infection-associated GN (SIAGN)

• Culture-proven, ongoing Staphylococcus aureus infection (blood cultures are frequently negative) – commonly done first after the biopsy.
• Concomitant glomerulonephritis with acute kidney injury.
• Hematuria and proteinuria.
• Renal biopsy: diffuse mesangial and intracapillary hypercellularity (sometimes crescents and necrosis) frequently with ATN.
• IgA and C3 containing glomerular immune complexes by immunofluorescence.
• Mesangial, frequently also peripheral glomerular capillary electron dense immune-type deposits by electron microscopy (subepithelial humps may or may not be present – seen in approximately 1/3 of cases).
Diagnostic difficulties in SIAGN

• Bacterial culture results are unavailable in a large percentage of patients despite characteristic clinical presentation and with kidney biopsies showing histologic typical features.
• Most patients are elderly with multiple co-morbidities, often treated empirically with multiple antibiotics. Cultures may become negative.
• Blood cultures may be negative in a large percentage of these cases. Cultures from the site of infection need to be taken.
• Also, clinical features of infection, in elderly patients can be subtle
SIAGN is NOT “Post-Staphylococcal glomerulonephritis”

- Many case reports and case series address this condition as post-staphylococcal glomerulonephritis.
- “Post” means that the infection is gone (such as in post-streptococcal glomerulonephritis). This is not true in most cases of SIAGN.
- Clearly differentiate the two conditions because postinfectious GN can be treated with steroids, whereas SAIGN and other forms of active ongoing infection-associated GN should not.
Post-streptococcal versus SIAGN

Post-infectious /post-streptococcal glomerulonephritis

“Post” – after infection resolves with or without anti-microbial treatment

Latent period of 1 to 4 weeks with normal state of health

Acute onset of glomerulonephritis, usually supportive treatment; sometimes steroid treatment may help.

**Biopsy:**

**LM:** Proliferative GN

**IF:** C3 dominant granular deposits with or without IgG

**EM:** subepithelial humps, some mesangial deposits

Staphylococcus infection associated glomerulonephritis (IgA dominant)

Infection is active and ongoing when the glomerulonephritis develops

Therapy: Antibiotics, sometimes requires amputation or debridement of infected area. **Avoid steroids!**

Glomerulonephritis will resolve after infection is treated, provided underlying chronic kidney injury is not severe.

**Biopsy:**

**LM:** Variable degree of glomerular proliferative changes;

**IF:** C3 and IgA dominant deposits.

**EM** mesangial and glomerular capillary deposits, sometimes humps
Common associations with SIAGN

- **Predisposing Co-morbidities**
  1. Diabetes Mellitus
  2. Post-surgery
  3. Post-trauma
  4. Prosthetic heart valves
  5. Intravenous drug use
  6. Hepatitis C
  7. Underlying malignancy

- **Sites of Infection**
  1. Diabetic foot ulcers
  2. Cellulitis
  3. Pneumonia
  4. Endocarditis
  5. Infected surgical sites
  6. Osteomyelitis
  7. Visceral abscess
  8. Septic arthritis
  9. Infected pace-maker, heart valves, indwelling catheters, iv lines
  10. Infected abdominal mesh
  11. Dental infection
  12. Amputated limbs in diabetic patients
Experience at Ohio State University Medical Center

- During the period 2004 to 2014, out of 7,092 native kidney biopsies, 67 (0.94%) had culture proven SIAGN.
- At least 35 additional biopsies with typical histologic features and clinical presentation of SIAGN, but no documented culture results.
Clinicopathologic characteristics of the 68 cases of culture positive Staphylococcal infection associated glomerulonephritis from 2004 to 2014 at the Ohio State University Medical Center.

</table>
Morphology of SIAGN: Light Microscopy

- Spectrum of glomerular changes.
- ATN
- RBC casts
Immunofluorescence: IgA of variable intensity. C3 usually bright

- Mild mesangial IgA
- Moderate mesangial IgA
- Prominent mesangial IgA
- C3 staining
Electron microscopy

“Humps” may or may not be seen.

Mesangial deposits (always present)
Subendothelial deposits (sometimes large)
Subepithelial “humps” (35% of cases)

Based on morphology alone, differentiating SIAGN from IgA nephropathy is difficult

</table>
If you have a patient with AKI, proteinuria, hematuria and some evidence of infection (other than upper respiratory tract) and particularly if the patient has comorbidities, such as diabetes, morbid obesity, cancer, etc. and the renal biopsy diagnosis is IgA nephropathy, seriously consider *staphylococcus infection* in the background.
Case History (Case #2)

- 51-year-old Caucasian male
  - Right wrist pain and swelling
  - MRI 2 weeks prior to presentation: tenosynovitis.
  - Purpura on legs progressed to burning erythematous rash on legs, thighs, buttocks, lower abdomen, arms.
  - Abdominal pain – X-ray – Colonic distention
  - Patient was started on steroid (Medrol Dosepak – methylprednisolone)
IV methyl prednisolone (125 mg) with 2 g ceftriaxone on day of transfer to OSU medical Center.

Temporary relief only.
Laboratory Data on Admission

Serum creatinine: 0.9 mg/dl on admission

Urinalysis: Trace blood, no protein, no WBCs, no RBCs, few granular casts

WBC count: 9,200/\mu l
Differential: 85% PMNs, 7.2% Lymphs, 5.9% Monos ESR: 43 mm

Blood cultures negative

Arthrocentesis
  Unfortunately, only scant fluid obtained, no cell count available
  No crystals by polarized light
Additional Labs

- ANCA – Negative
- ANA – Negative
- RF – < 20
- Total IgG – 452
- Total IgA – 302
- Hepatitis B, C – Negative
- Lyme Abs - Negative
- Serum immunofixation - negative
Rash - Palpable Purpura
Skin Bx - Leukocytoclastic vasculitis
Skin Bx immunofluorescence staining – IgA in arteriolar walls
Presumptive Diagnosis:
Henoch Schönlein Purpura
(IgA vasculitis)
• Findings not in favor of HSP:
  – **Monoarticular arthritis**
  – Persistence and worsening of symptoms despite high dose steroids
  – Joint pain preceded skin rash
  – Adult onset presentation
Hospital Day 4

- Progression of rash to multiple bullous lesions on upper and lower extremities
Renal function worsened

Urine output fell.

Patient became febrile.

Systolic blood pressure less than 100 mm Hg.

Leukocytosis – WBC 17,900/μl
Segmental necrosis with early crescent formation
Immunofluorescence panel alb, IgG, IgA, IgM, C1q, C3, Fibrinogen, kappa and lambda

IgA (granular mesangial staining)
C3 (coarse granular mesangial staining)
Electron dense immune-type mesangial deposits
Biopsy Diagnosis

Diffuse proliferative glomerulonephritis with IgA and C3 containing immune complex deposits.

Note: The biopsy findings raise the possibility of IgA-dominant Staphylococcus infection-associated acute glomerulonephritis.

(PROBABLY NOT HENOCH-SCHÖNLEIN PURPURA OR IgA NEPHROPATHY)
• Repeat MRI of the wrist

**MRI Results** - Extensive osteomyelitis of the distal radius, all carpal bones and 2nd and 3rd proximal metacarpals. Extensive overlying cellulitis, myositis, and fasciitis.

Blood cultures: still negative
Further management and follow-up

- Debridement of the wrist wound

- Cultures from synovium and bone: **Methicillin-Sensitive Staphylococcus aureus (MSSA)**

- Started on Nafcillin infusion for MSSA – 6 weeks

- Renal function stabilized at serum creatinine of 2.0mg/dl.

- Follow up after completion of antibiotics
  - Serum creatinine decreased to 1.3mg/dl
  - Urinalysis – negative for blood and protein
One of the most common diagnostic pitfalls in renal pathology
Clinically very important

- IgA nephropathy
- Henoch-Schönlein purpura
- IgA-dominant Staphylococcus infection associated GN

Carefully differentiate between these diseases, all show IgA immune complex deposits – treatments significantly different.

Biopsy findings alone are not sufficient to distinguish between these.
Clinical history is very important.
Blood cultures often negative, local wound cultures required.
Need to have a high level of suspicion and alert your nephrology colleagues, to look for possible infection.
Idiopathic Henoch-Schönlein Purpura (HSP) vs. HSP-like presentation in Staphylococcus infection associated glomerulonephritis

<td>Usually poor renal outcome.</td>
</tr>
</tbody>
</table>
Conclusions

• Staphylococcus infection became the most common cause of infection-associated GN in the US (and probably in most developed countries), particularly in adults and in the elderly

• AKI + Proliferative GN with IgA deposits (frequently with severe proteinuria): Consider infection, in particular staphylococcus infection

• Infection may not be clinically obvious – needs to be carefully looked for.

• Blood cultures may be negative. Local wound cultures important.

• SAIGN should be clearly distinguished from IgA nephropathy/HSP.

• Infection is active, ongoing; therefore avoid the term “post-infectious” (post-staphylococcal) glomerulonephritis

• Treatment of the infection is most important. Immunosuppression should be avoided
