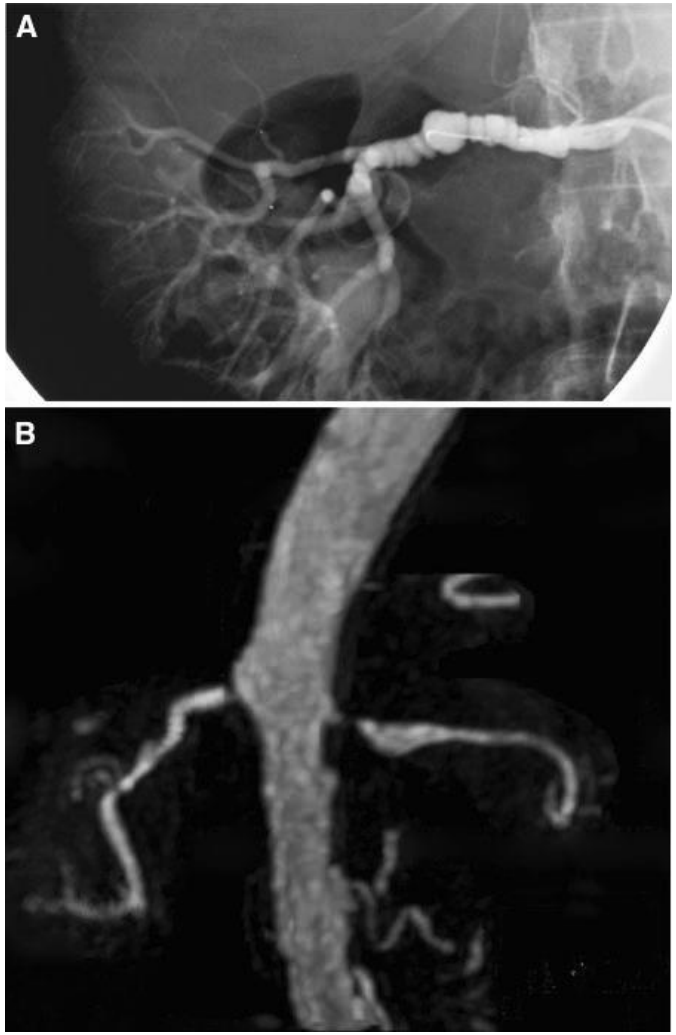
Two forms of renal artery leasions



A, Angiogram from a patient with FMD with lesions characteristic of medial fibroplasia. The "string-of-beads" appearance typically develops in the mid portion of the vessel from circumferential webs within the vessel. These lesions may progress, particularly in smokers.

B, MRA from an individual with atherosclerotic disease affecting the renal arteries. These lesions commonly arise near the ostium of the vessel and may be an extension of aortic plaques.

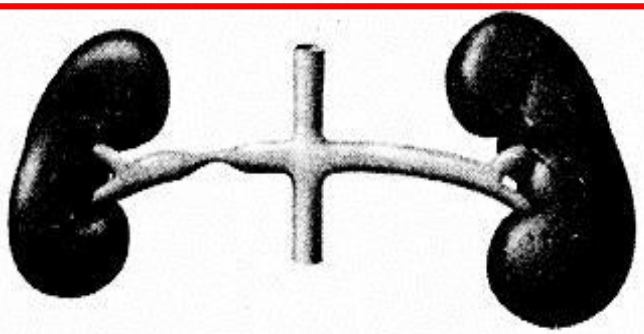
UNILATERAL RENAL ARTERY STENOSIS



Reduced renal perfusion

↓

↑ Renin-angiotensin system (RAS)
↑ Renin
↑ Angiotensin II
↑ Aldosterone

↓

Angiotensin II–dependent hypertension

Increased renal perfusion

↓

Suppressed RAS

Increased Na^+ excretion (pressure natriuresis)

Effect of blockade of RAS

Reduced arterial pressure

Enhanced lateralization of diagnostic tests

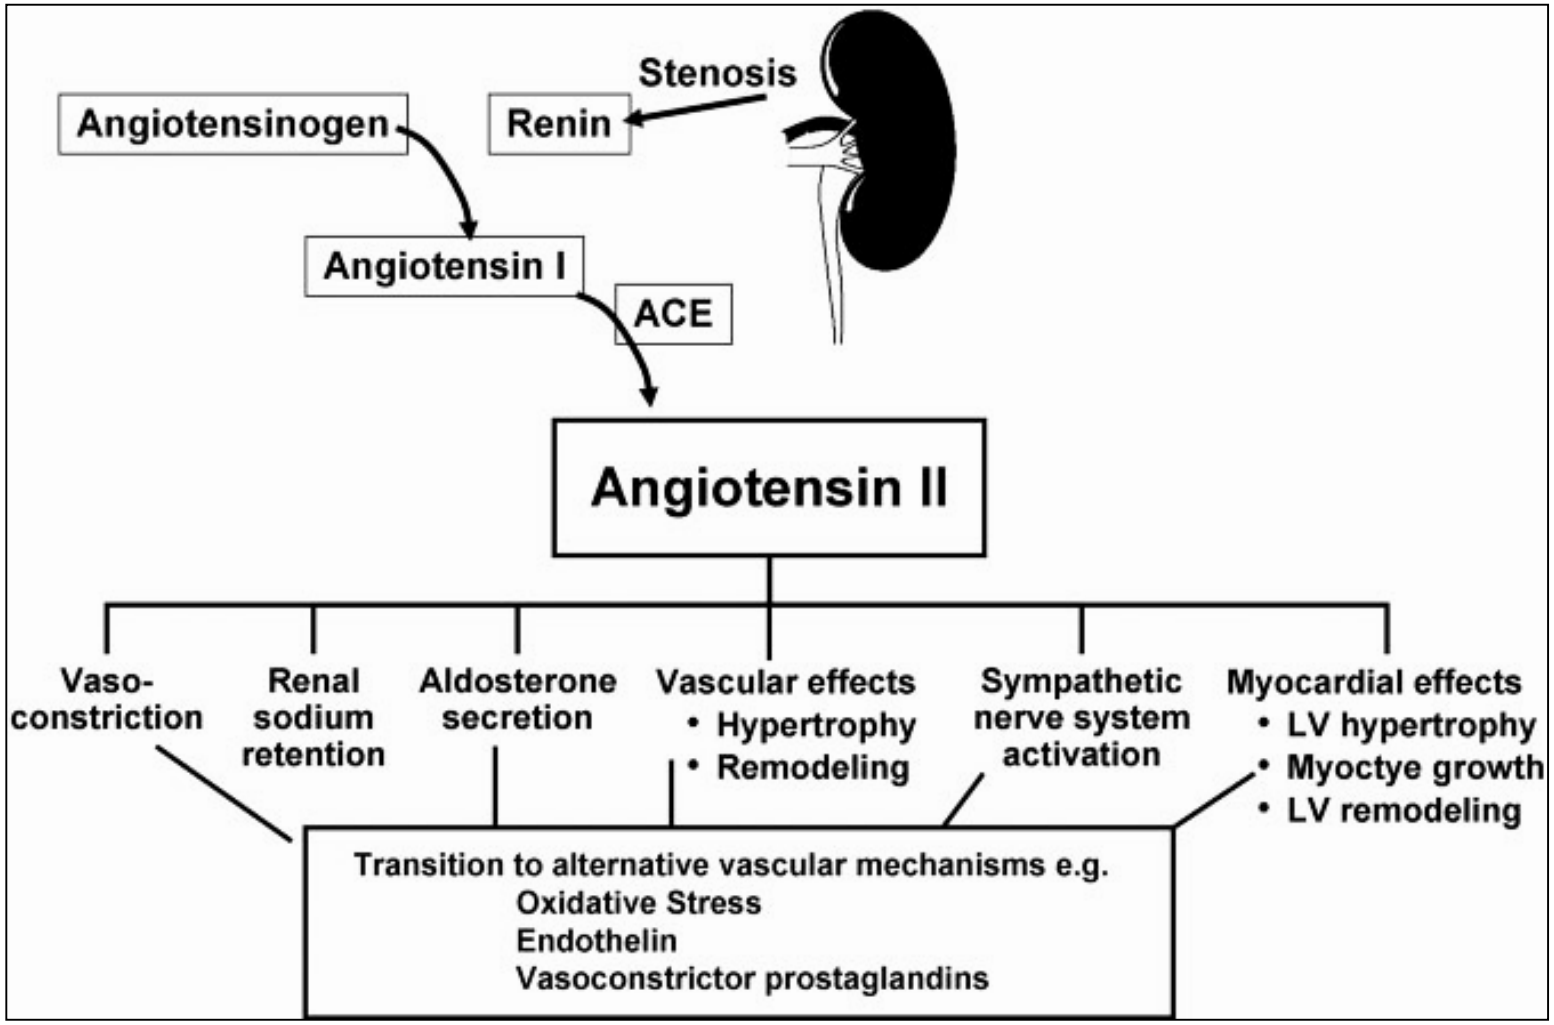
Glomerular filtration rate (GFR) in stenotic kidney may fall

Diagnostic tests

Plasma renin activity elevated

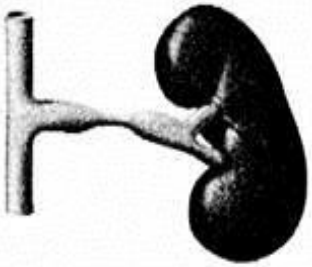
Lateralized features, e.g., renin levels in renal veins, captopril-enhanced renography

Pressor mechanisms identified in renovascular hypertension



Garovic V.D. and Textor S.C., Circulation. 2005; 112: 1362-1374

BILATERAL RENAL ARTERY STENOSIS



Bilateral

Stenosis of solitary kidney

Reduced renal perfusion

↑ Renin-angiotensin system (RAS)
↑ Renin
↑ Angiotensin II
↑ Aldosterone

Impaired Na^+ and water excretion

Inhibit RAS

Volume expansion

Normal or low angiotensin II

Increased arterial pressure

Effect of blockade of RAS

Reduced arterial pressure only after volume depletion

May lower GFR

Diagnostic tests

Plasma renin activity normal or low

Lateralized features: none

Measured fall in arterial pressure and blood flow across stenotic vascular lesion induced in experimental animals

These data indicate that „critical" lesions require 70-80% luminal obstruction before hemodynamic effects can be detected

Blood Oxygen Level–Dependent (BOLD) magnetic resonance imaging technique

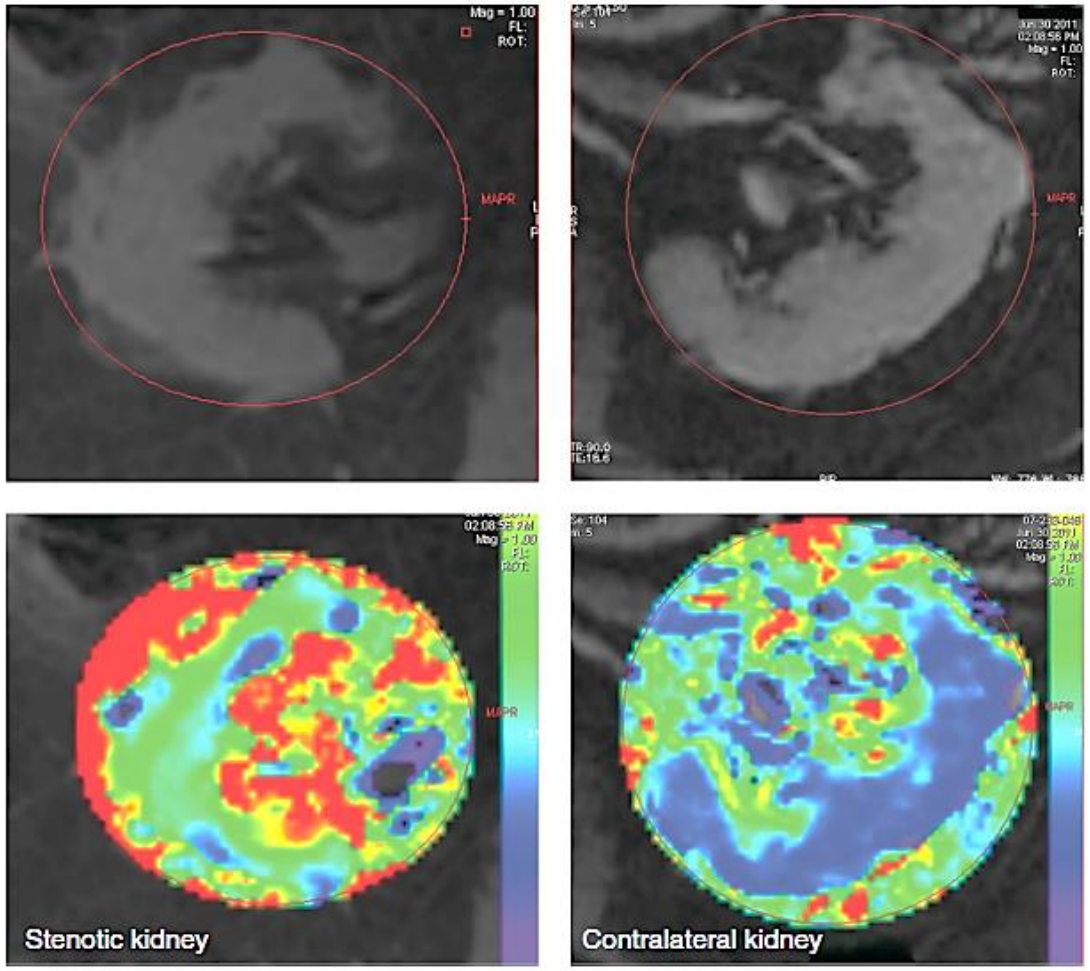

Figure 5 | Blood-oxygen-level-dependent (BOLD) magnetic resonance (MR) images with parametric maps depicting R2* levels that correspond to tissue levels of deoxyhemoglobin in axial images of the kidneys. Both of these kidneys had high-grade renal arterial stenosis with velocities >400 cm/s. Serum creatinine was >3.6 mg/dl, although the patient was treated with angiotensin receptor blockers and diuretics. The larger kidney (right panel, left kidney) has well-preserved cortical oxygenation (blue zone) and a normal corticomedullary oxygen gradient. The smaller kidney (left panels) is developing overt cortical hypoxia with rising R2* levels and expanding zone of medullary hypoxia (inner red zone). These functional imaging tools may assist in defining kidneys that are 'at risk' from critical vascular occlusion, yet remain 'salvageable' from the point of view of restoring renal blood flow (see text).

Rundback, M.D., Joseph M. Massaro, Ph.D., Ralph B. D'Agostino, Sr., Ph.D., and Lance D. Dworkin, M.D., for the CORAL Investigators*

ABSTRACT

BACKGROUND

Atherosclerotic renal-artery stenosis is a common problem in the elderly. Despite two randomized trials that did not show a benefit of renal-artery stenting with respect to kidney function, the usefulness of stenting for the prevention of major adverse renal and cardiovascular events is uncertain.

CONCLUSIONS

Renal-artery stenting did not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or chronic kidney disease. (Funded by the National Heart, Lung and Blood Institute and others; ClinicalTrials.gov number, NCT00081731.)

From the University of Toledo, Toledo, OH (C.J.C.); Rhode Island Hospital (T.P.M., L.D.D.) and Alpert Medical School of Brown University (T.P.M., L.D.D.) — both in Providence; Harvard Clinical Research Institute (D.E.C., J.M.M., R.B.D.), Beth Israel Deaconess Medical Center (D.E.C.),

CURRENT OPINION

Where now in the management of renal artery stenosis? Implications of the ASTRAL and CORAL trials

James Ritchie, Helen V. Alderson, and Philip A. Kalra

Purpose of review

The neutral findings of Angioplasty and Stenting for Renal Artery Lesions and Cardiovascular Outcomes in Renal Artery Lesions trials have shown that unselected revascularization does not improve outcomes in atherosclerotic renovascular disease (ARVD). This review highlights recent translational, clinical and epidemiological studies and suggests directions for future research.

Recent findings

Imaging studies show that the degree of renal artery stenosis is not the most important determinant of outcome and response to therapies in ARVD. Porcine models have established a better understanding of the microvascular and inflammatory changes that occur in ARVD. Biomarkers of inflammation and cardiovascular dysfunction may be informative but do not yet help assess prognosis or response to treatment. Stem cell therapies show promise in animal models but have yet to translate into clinical practice. Analysis of patient subgroups with high-risk presentations of ARVD has provided new insights into treatment response and may guide future studies.

Summary

It is time to reframe thinking and research in ARVD. We need better ways to identify patients likely to benefit from revascularization and to improve response to treatment in these individuals. Many preclinical studies show promise, but these are often small scale and difficult to replicate. Future work should focus on establishing an international disease registry as a foundation for collaborative research.

*Department of Vascular and Endovascular Surgery, San Pietro-Fatebenefratelli Hospital, Rome, Italy
**Department of Nephrology, School of Medicine, Magna Graecia University of Catanzaro, Catanzaro, Italy

MATERIALS AND METHODS: we performed an observational study on a total of 55 patients to find predictive factors of the outcome of renal function after renal percutaneous transluminal angioplasty and stenting (RPTAs).

RESULTS: We found that uricemia, proteinuria and IR were higher at baseline in patients who worsened renal function after revascularization.

CONCLUSIONS: The identification of predictive factors (uricemia; proteinuria and RI) of chronic kidney disease (CKD) progression in patients with RAS undergone revascularization could be useful to predict renal long term outcome and to select patients that really could benefit of this.

Renovascular Hypertension Revisited: To intervene or not?

- Therefore, the assumption that restoring renal artery patency always protects the kidney is false. In addition, sometimes the revascularization procedure causes a worsening of kidney function, in addition to the high risk of major complications and increased economic costs associated with the procedure

Boehlke M. and Correa Barcellos F., Am J Kidney Dis., 2015, 65: 611-622

Factors favoring medical therapy plus revascularization for renal artery stenosis:

- Progressive decline in GFR during treatment of hypertension
- Failure to achieve adequate BP control with optimal medical therapy
- Rapid or recurrent decline in GFR in association with a reduction in systemic pressure
- Decline in GFR during therapy with ACE inhibitors or ARBs
- Recurrent congestive heart failure in a patient in whom left ventricular failure does not explain the cause (flash pulmonary edema)

Textor S.C., Clin J Am Soc Nephrol., 2014, 9: 1117–1123

Factors favoring medical therapy and surveillance of renal artery disease

- Controlled BP with stable renal function
- Stable renal artery stenosis without progression on surveillance studies (e.g., serial duplex ultrasound)
- Advanced age and/or limited life expectancy
- Extensive comorbidities that make revascularization too risky
- High risk for or previous experience with atheroembolic disease
- Other concomitant renal parenchymal diseases that cause progressive renal dysfunction (e.g., diabetic nephropathy) or severely reduced kidney size (< 7.0 cm)

Textor S.C., Clin J Am Soc Nephrol., 2014, 9: 1117–1123
